LuciSUN

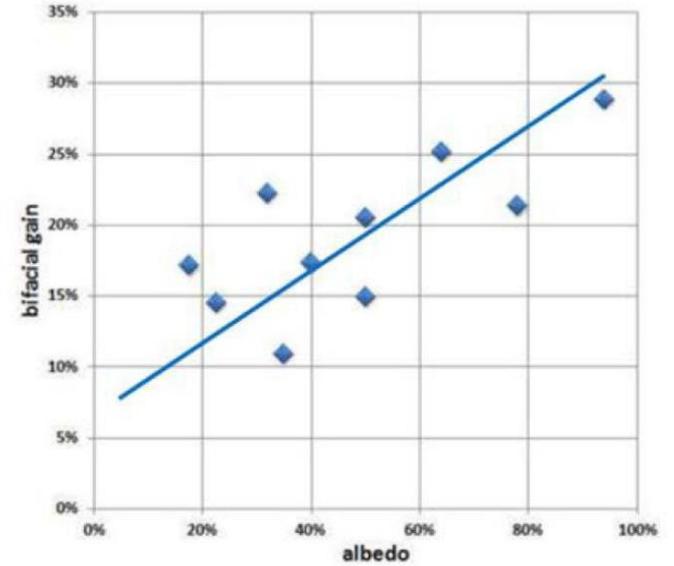

- What potential for bifacial PV? Why?
- Bifacial Energy Gain (BEG) to be expected?
- Parameters influencing BEG
- Uncertainties
- Risk assessment
- Current status of simulation tools
- Practical solutions for Energy Yield Assessments (EYA)

## General concepts on bifacial PV applications

NASA Earth observation, 2019

Kopecek, 2015

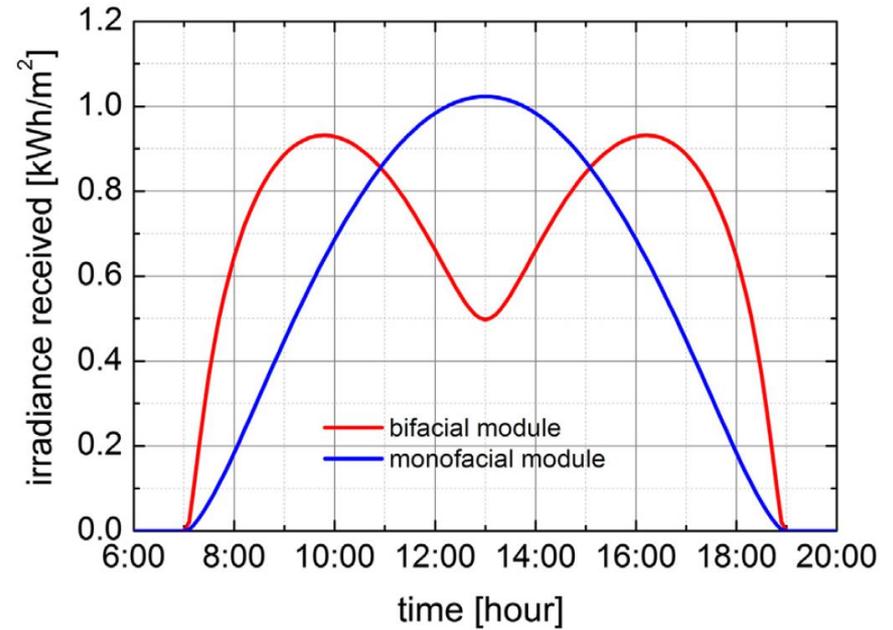

surface	albedo [%]
water	8
dry dark soil	13
grass	17-28
dry sand	35
dune sand	37
old snow	40-70
reflective roof coatings	80-90
fresh snow	75-95

PV plant with 1-axis trackers in Egypt

PV plants in Canada

Guo, 2013

## QUICKPOLL

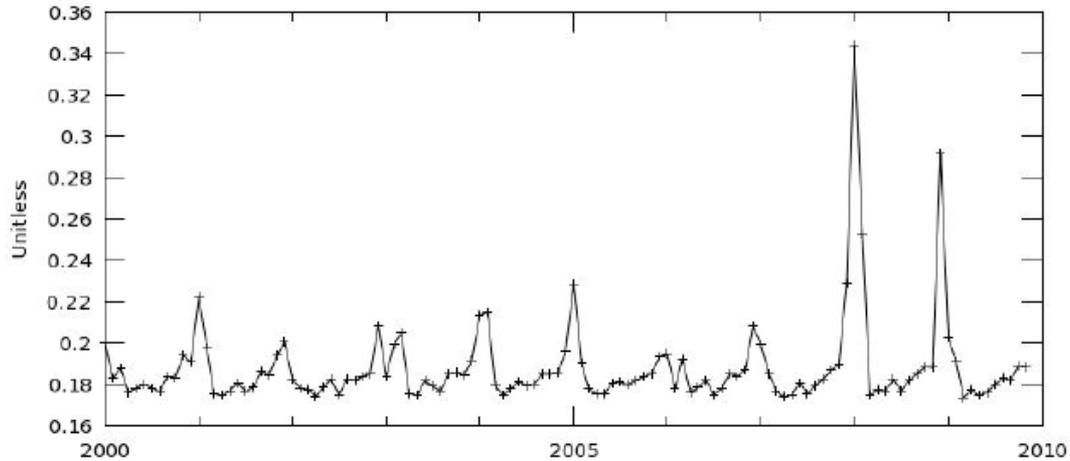

### 3. Bifacial promises a significant yield advantage. Why would you delay using bifacial?

Poll Results (single answer required):

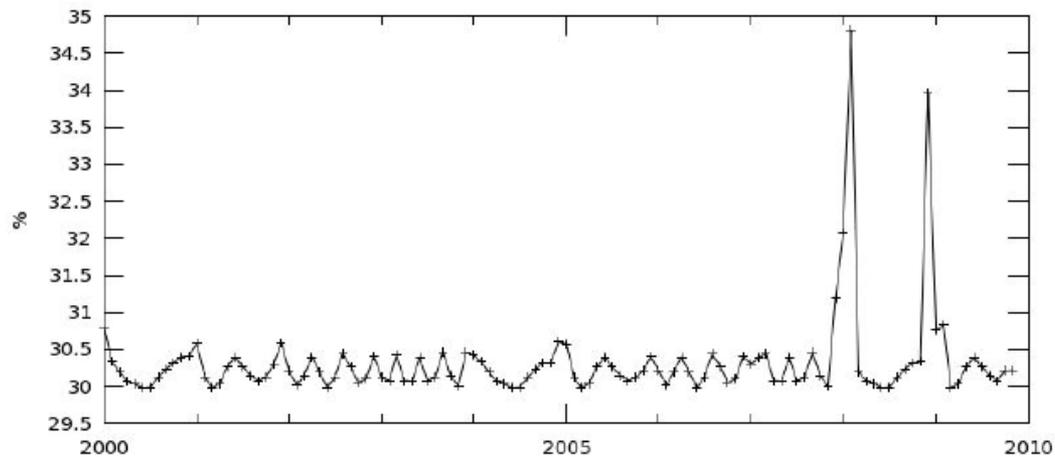

<b>a. Uncertainties about yield gains</b>	41%
<b>b. It requires changes in the BOS</b>	10%
<b>c. Unsure/negative feeling about Glass-glass</b>	8%
<b>d. For other reasons</b>	15%
<b>e. I am ready to use bifacial now!</b>	26%

### Irradiance model

#### Rear irradiance heterogeneity

- Rear side irradiance heterogeneity for HSAT or fixed-tilt (kWh/m<sup>2</sup>/year)

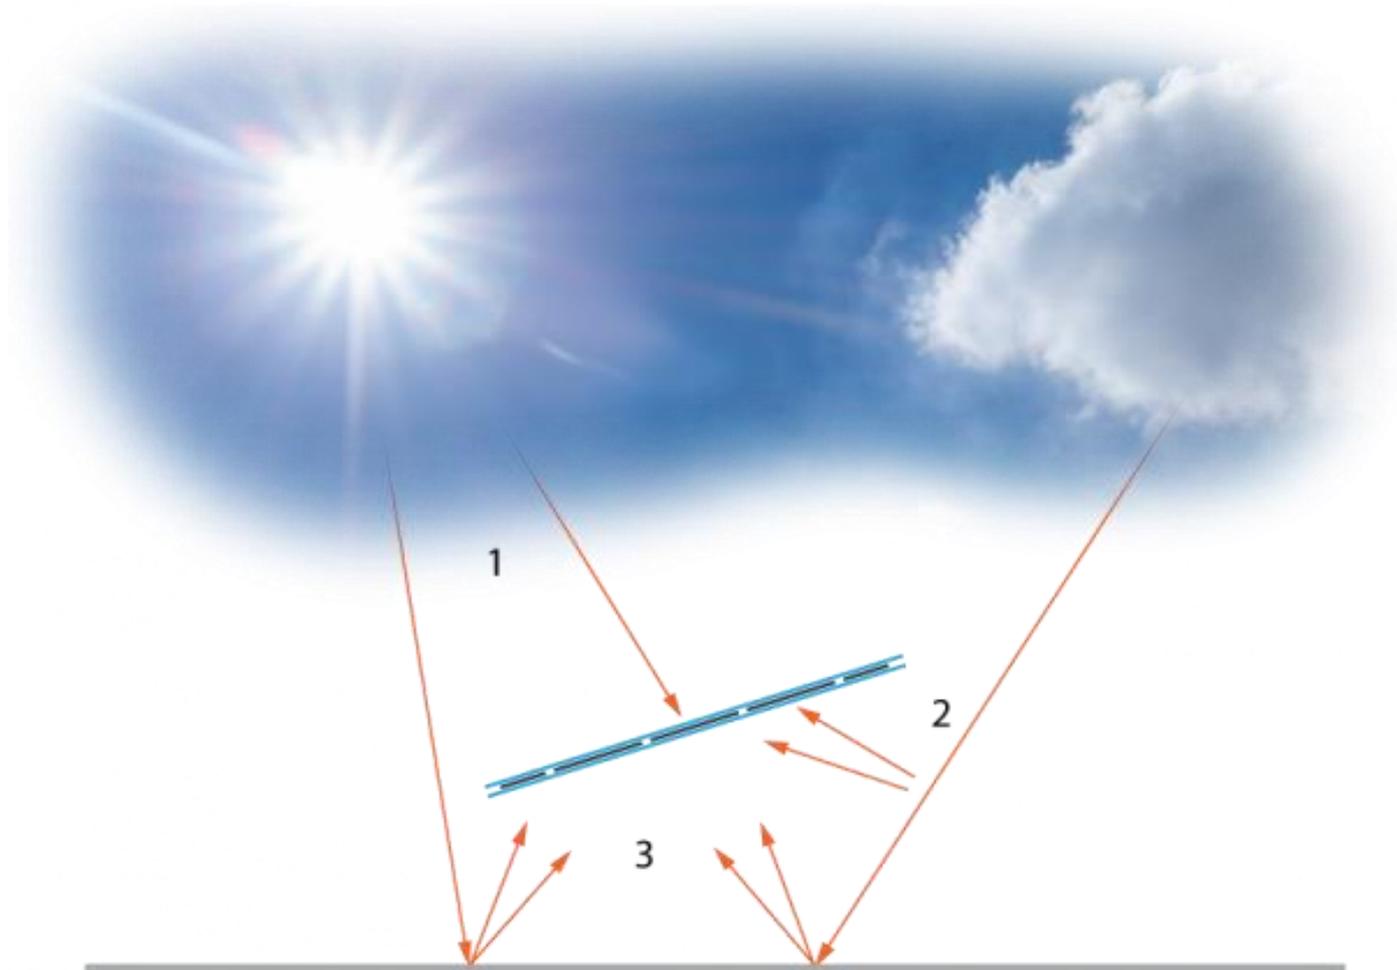

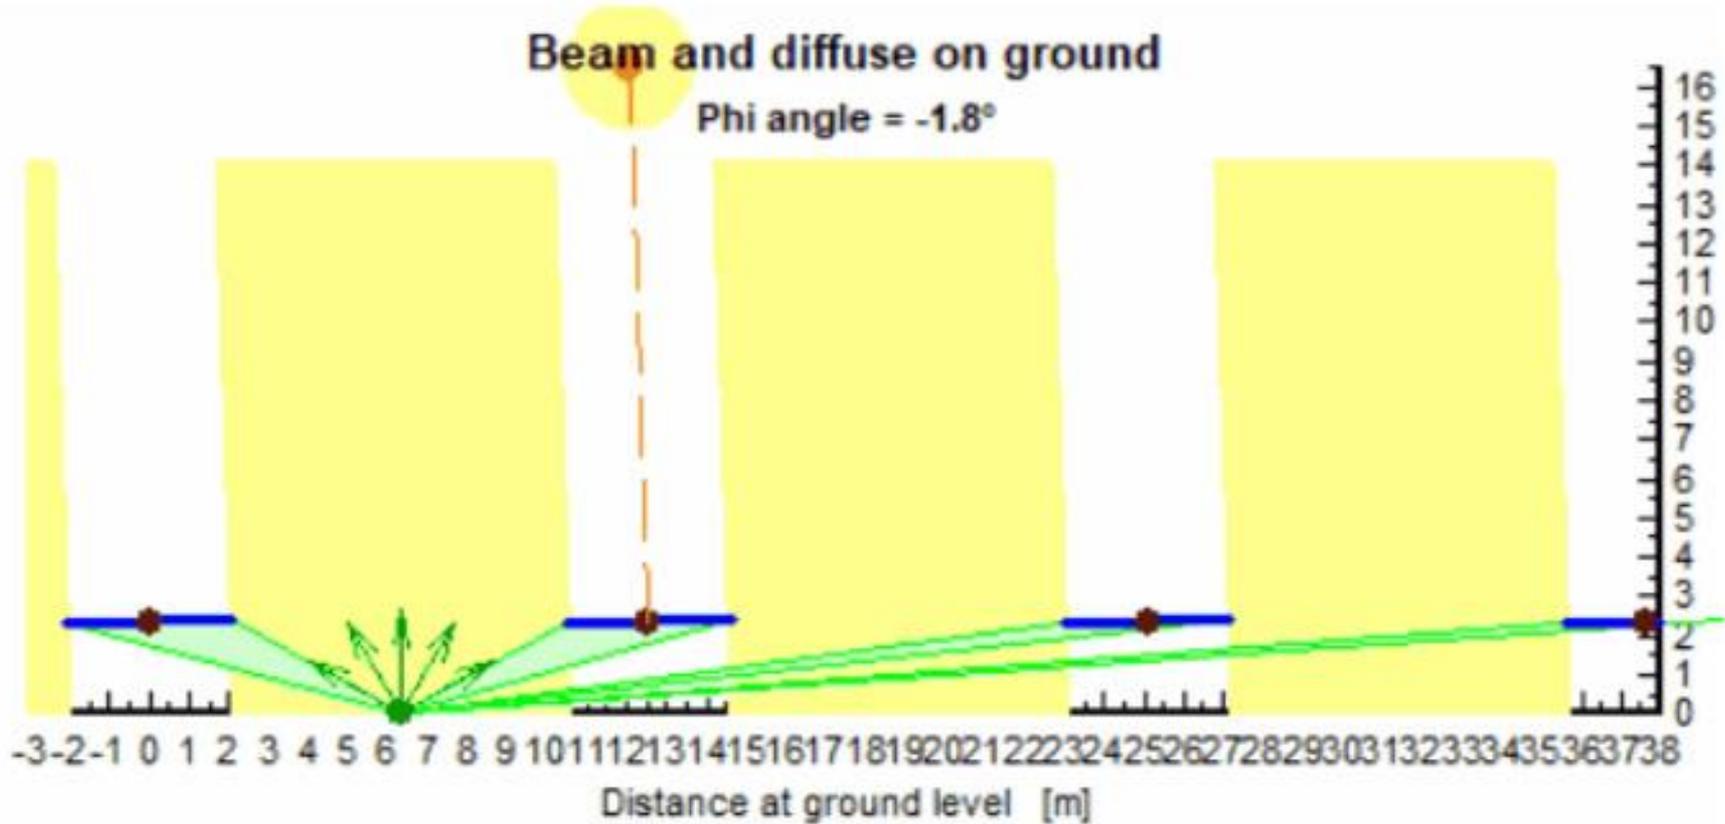

- Illustrations for Cairo (DNI=1760 kWh/m<sup>2</sup>), albedo=0.2, equivalent GCR=63%, fixed-tilt=30°, elevation=60cm

Simulations for Cairo, Dupuis, 2016

## Bifacial PV simulation: state of the art

Bi-facial system definition

General Simulation Parameters Unlimited Trackers 2D model

**Standard bifacial model involving tracker with horizontal axis**  
 You can play with the shed's parameters as you like for parametric analysis.  
 The simulation will use the parameters determined from the system (checkboxes checked)

**Orientation parameters**  
 According to system:  
 Axis azimuth: 0.0  
 Phi min: -60.0  
 Phi max: 60.0  
 Uses backtracking

**Trackers and ground parameter**  
 Pitch: 12.00 m  
 Shed total width: 4.04 m  
 => Profile angle limit: -70.2°  
 Height above ground: 3.00 m  
 Ground albedo: 20.0 %

**Irradiance on ground**  
 21 June 13:40  
 Phi angle (without limits): -20.0°  
 Beam clear sky: 833 W/m<sup>2</sup>  
 Global fraction on Ground: 94.7 %

**Daily irradiations for clear sky**  
 Month: June  
 Beam clear sky: 7.4 kWh/m<sup>2</sup>  
 Diffuse clear sky: 1.8 kWh/m<sup>2</sup>  
 Beam fraction on Ground: 54.1 %  
 Diffuse fraction on Ground: 67.0 %  
 Global fraction on Ground: 57.4 %

**Beam and diffuse on ground**  
 Phi angle = -20.0°

**Graph**  
 Global on ground  
 Hour of day: 10:49  
 Sun profile angle: 70°

## Timing

Rendering time depends strongly on the output image resolution, the number of light sources, scene complexity, the importance of indirect illumination, and the desired accuracy. Rendering time depends weakly on the materials used, emitting surface dimensions and output distributions, and the number of images rendered under the same lighting conditions (since diffuse indirect values may be reused just like radiosities).

A low resolution rendering of an empty space with a single light source will take a few seconds on a modern workstation (eg. Silicon Graphics IRIS or Sun SPARCstation). A high resolution rendering of a moderately complex office space with a direct lighting system will take about 1 hour on the same machine. The same rendering with daylight entering through venetian blinds will take about 2 hours. If the direct lighting system is replaced by an indirect hanging system, the rendering time will increase to about 4 hours. A large auditorium with 100 pendant fixtures will take about 12 hours to render at high resolution. An atrium space with significant indirect illumination could take as long as 20 hours. Such a rendering could be distributed among 20 workstations and be done in close to 2 hours. A 30 second walk-through animation of a large auditorium would take approximately 3 weeks to compute on a single workstation. This work could be distributed among 10 workstations and be done in a little more than 2 days.

Selection of on PV cell among PV generator

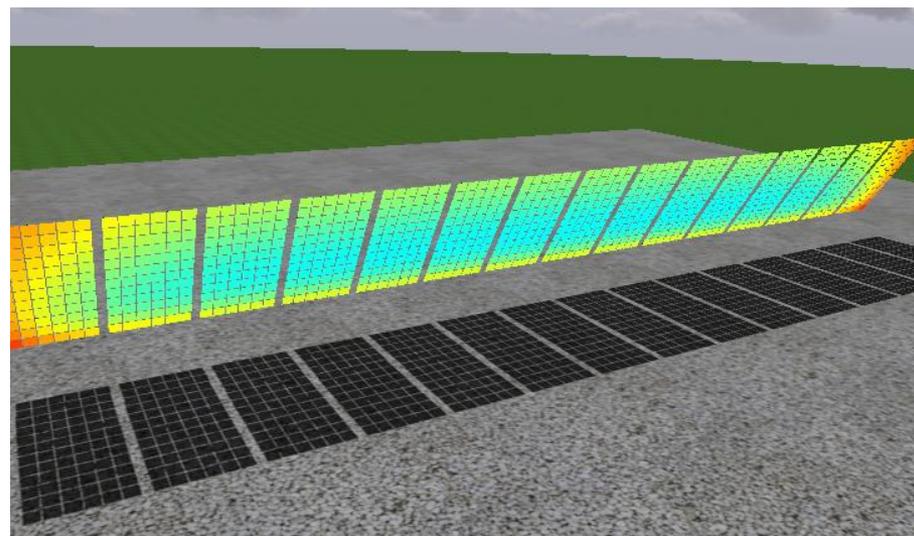

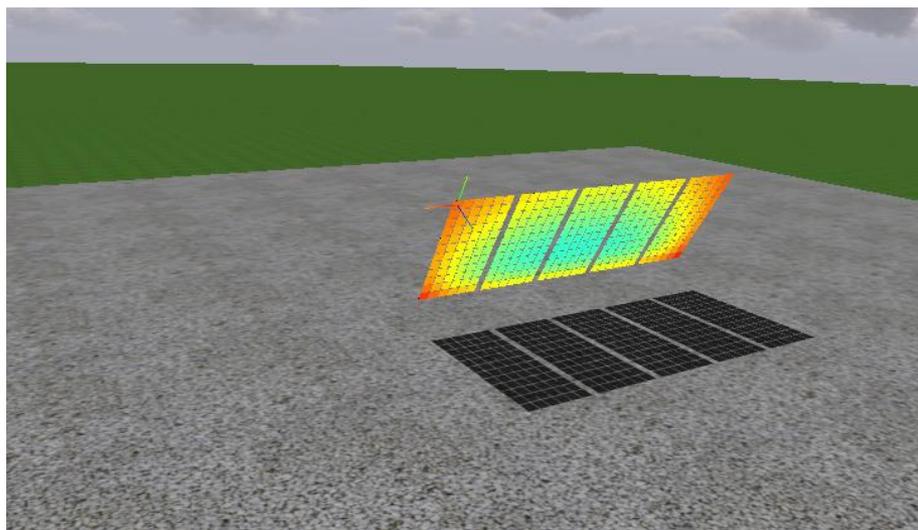

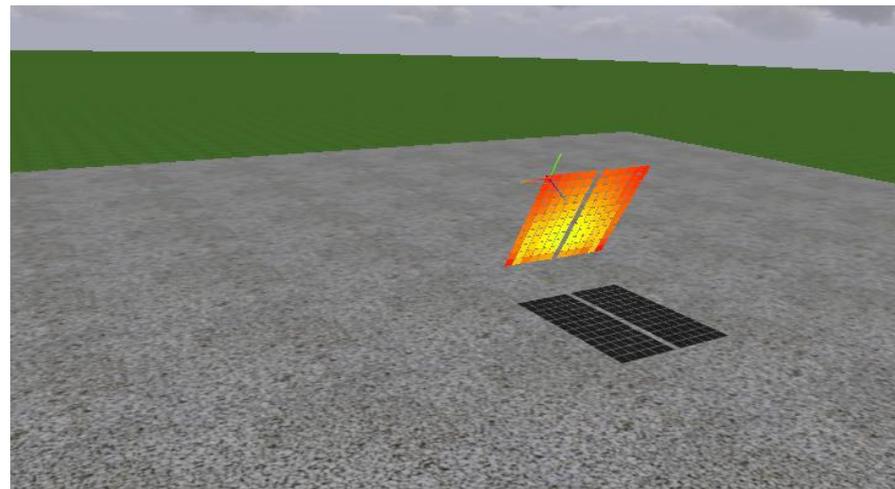

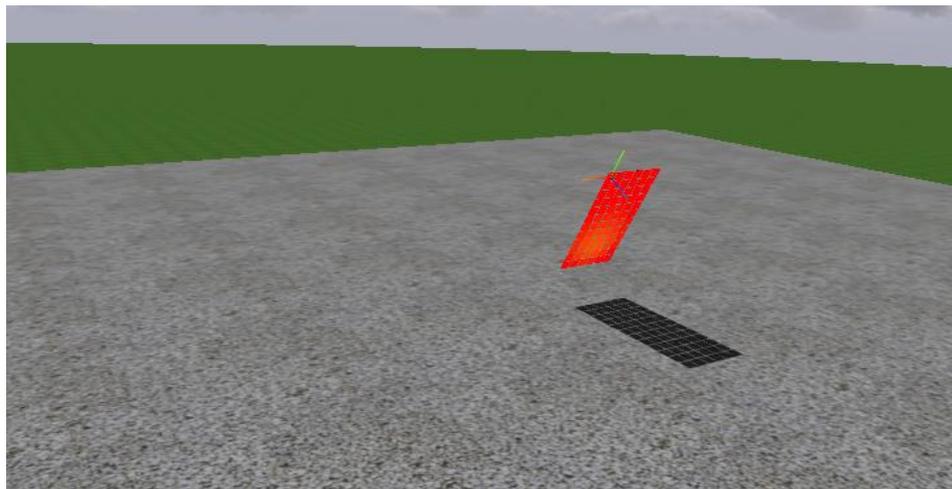

Backside irradiance from direct, diffuse and reflected components

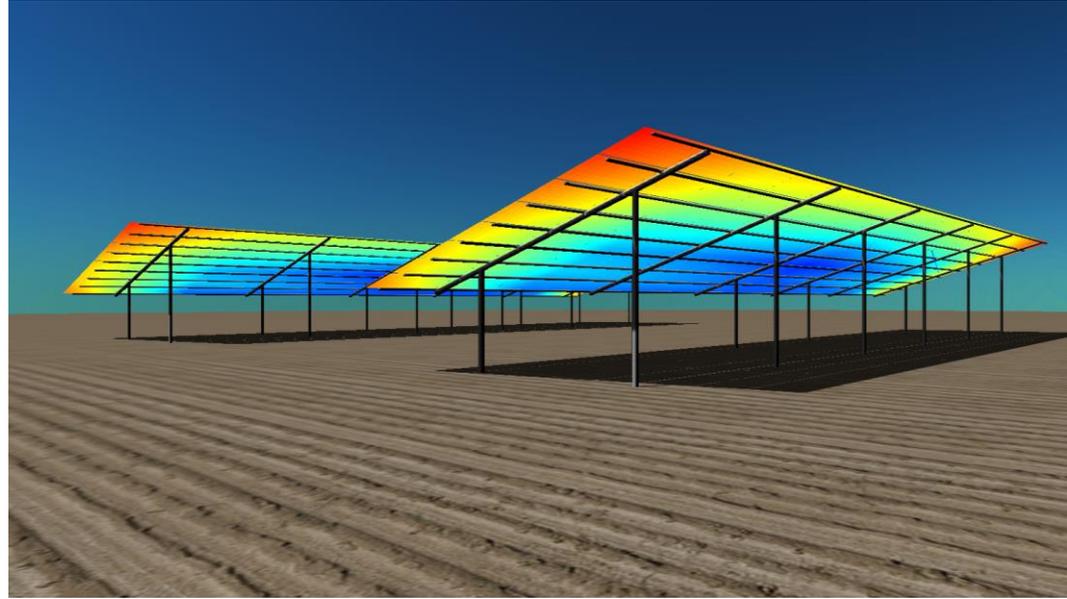

- 3D view generation for whole PV generator
- 206,000 rays
- 10 to 20 ms per picture

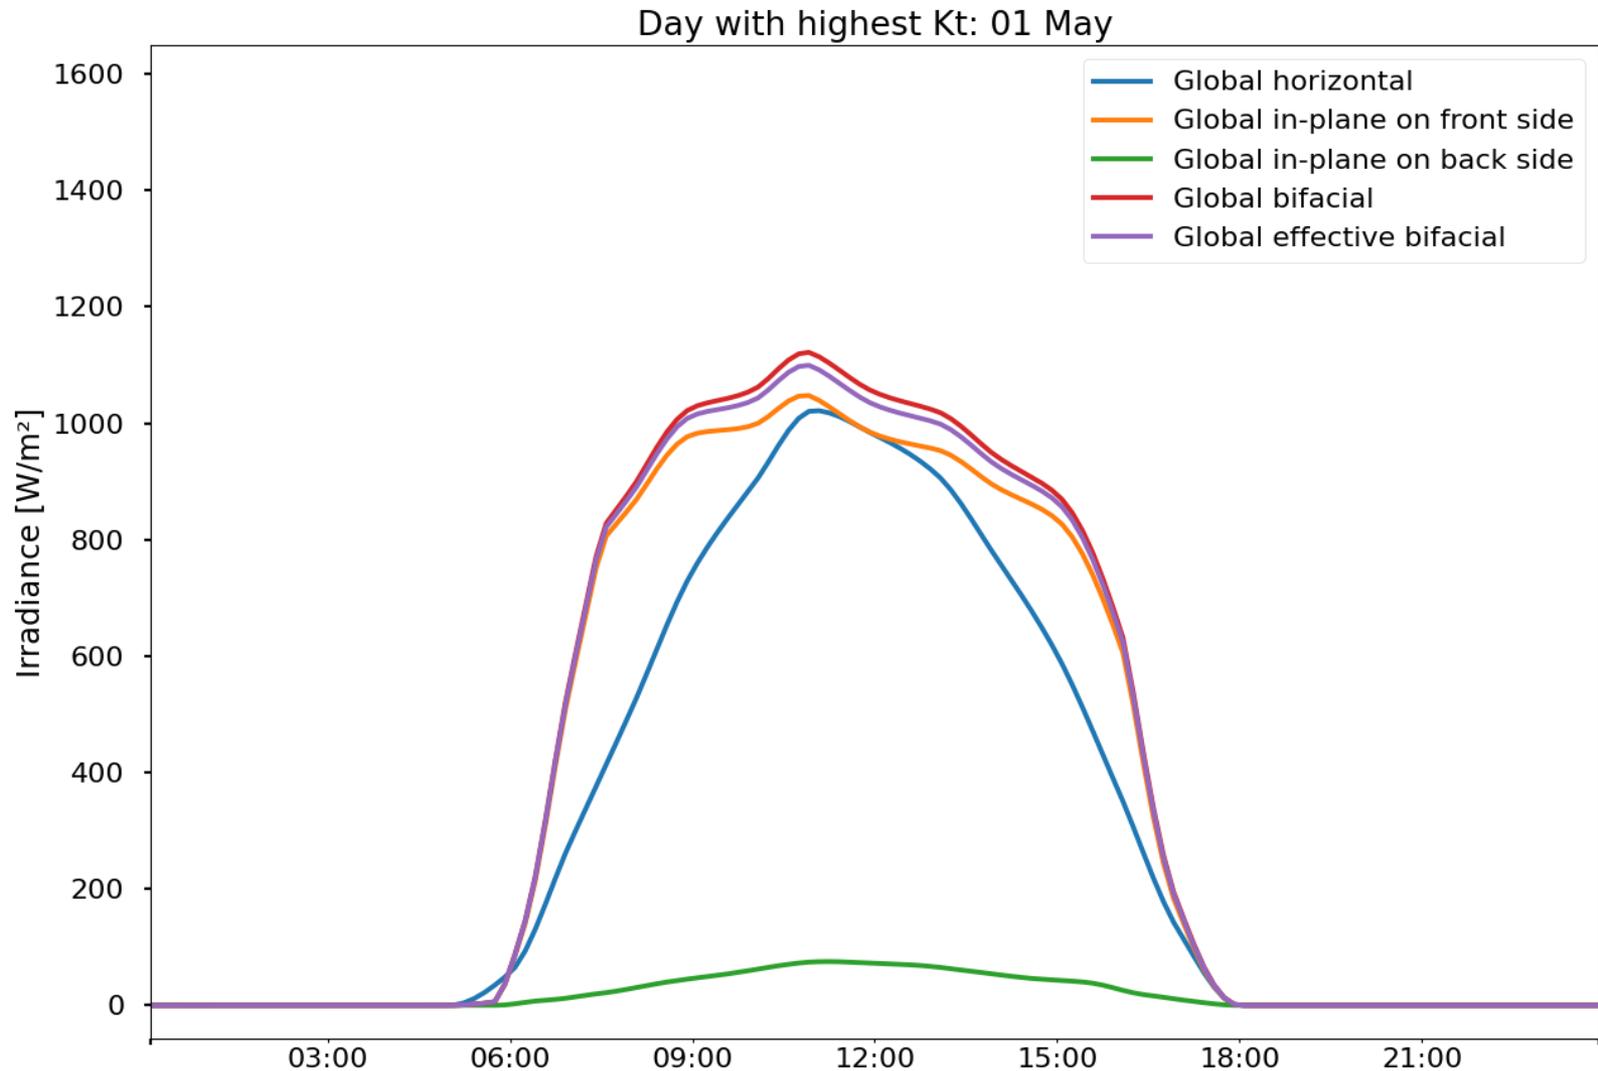

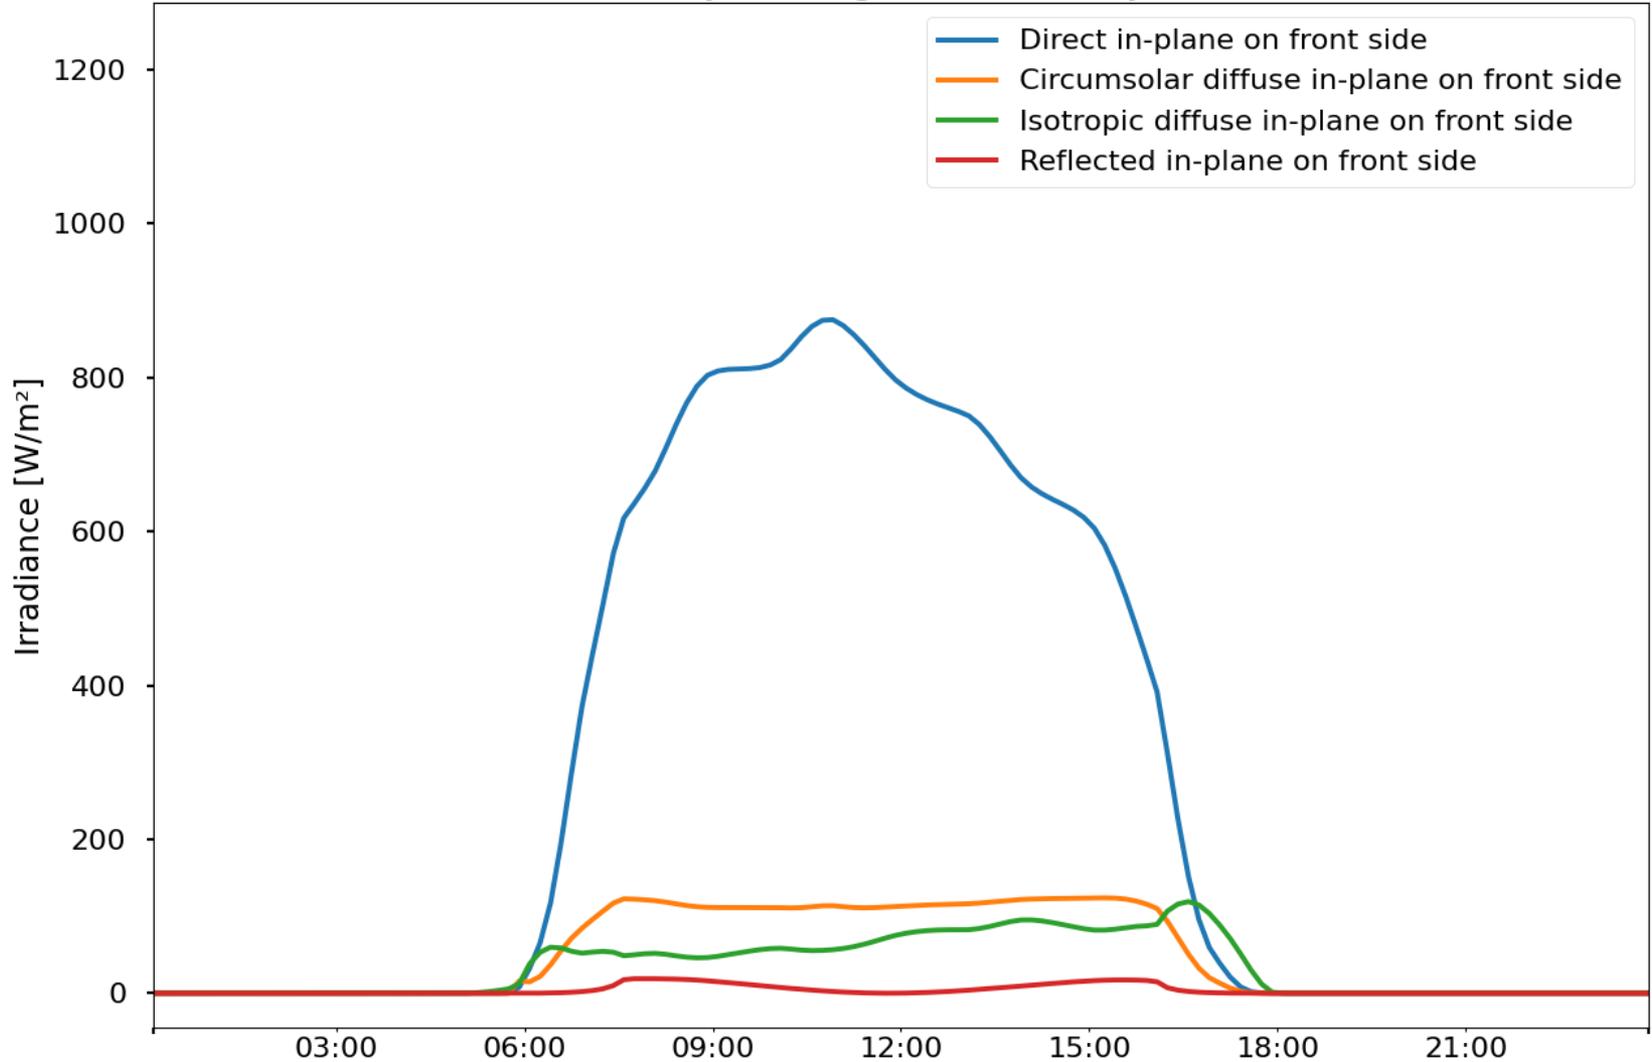

Direct reflected irradiance on back side

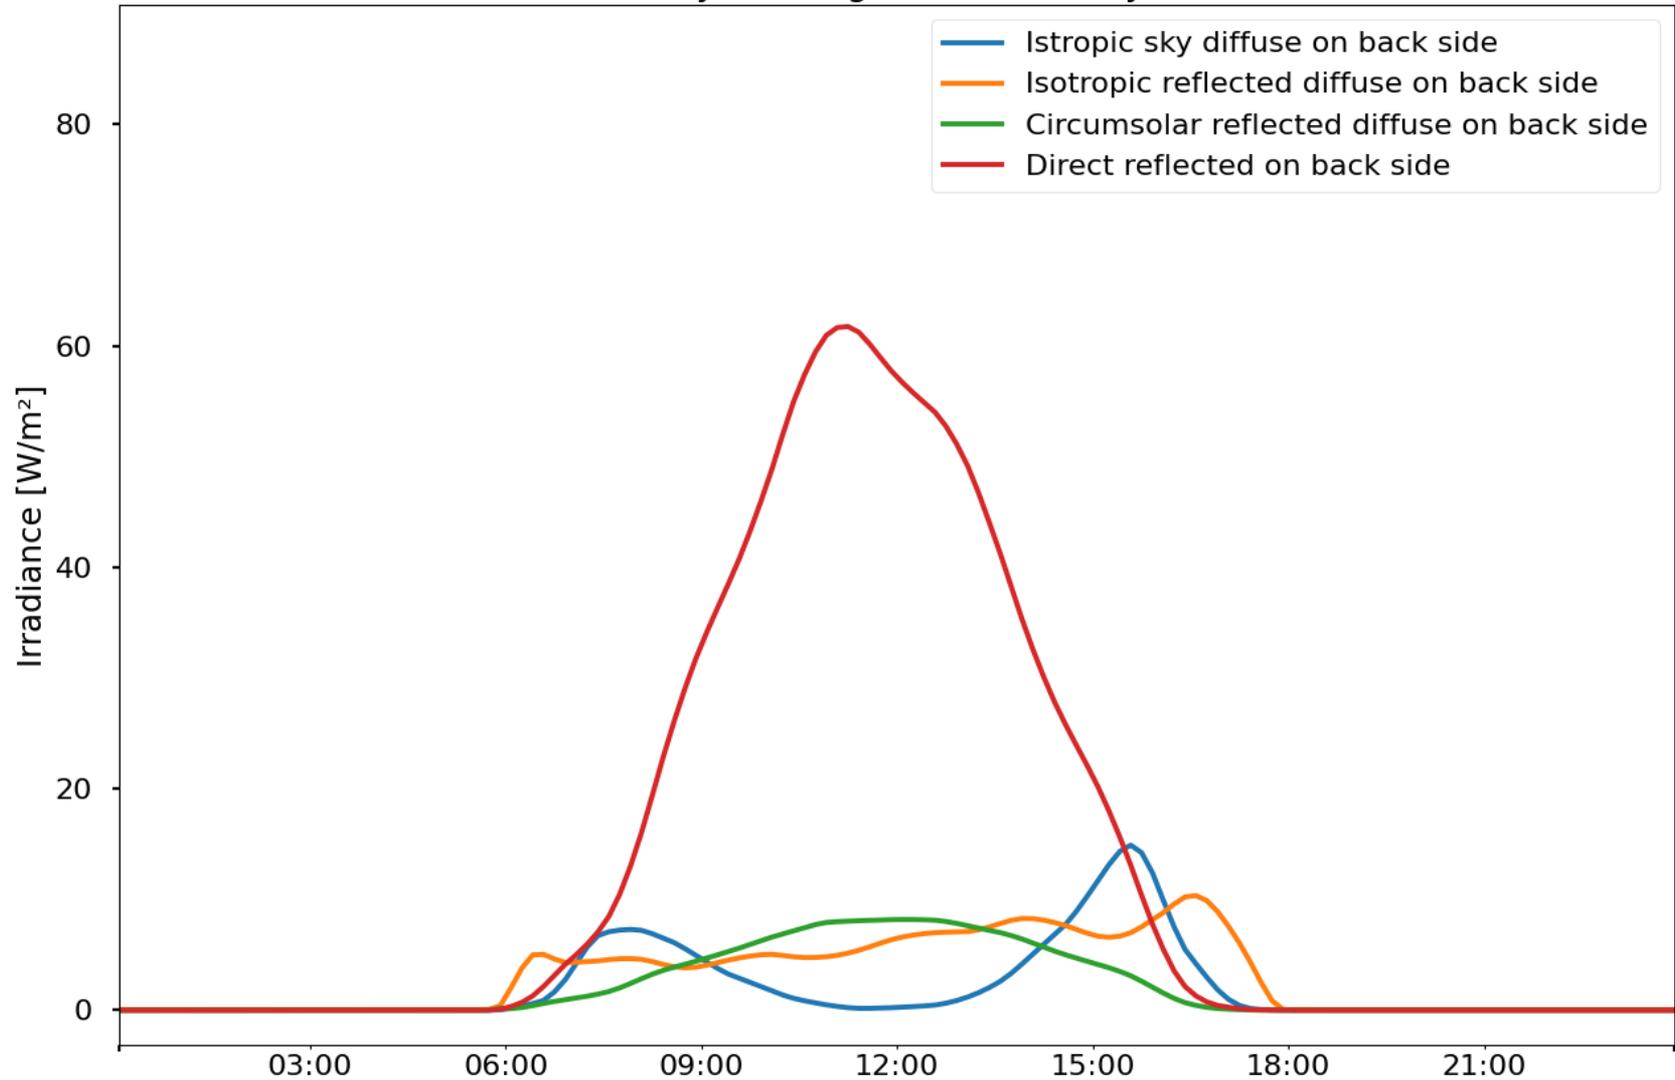

Isotropic diffuse sky irradiance on back side

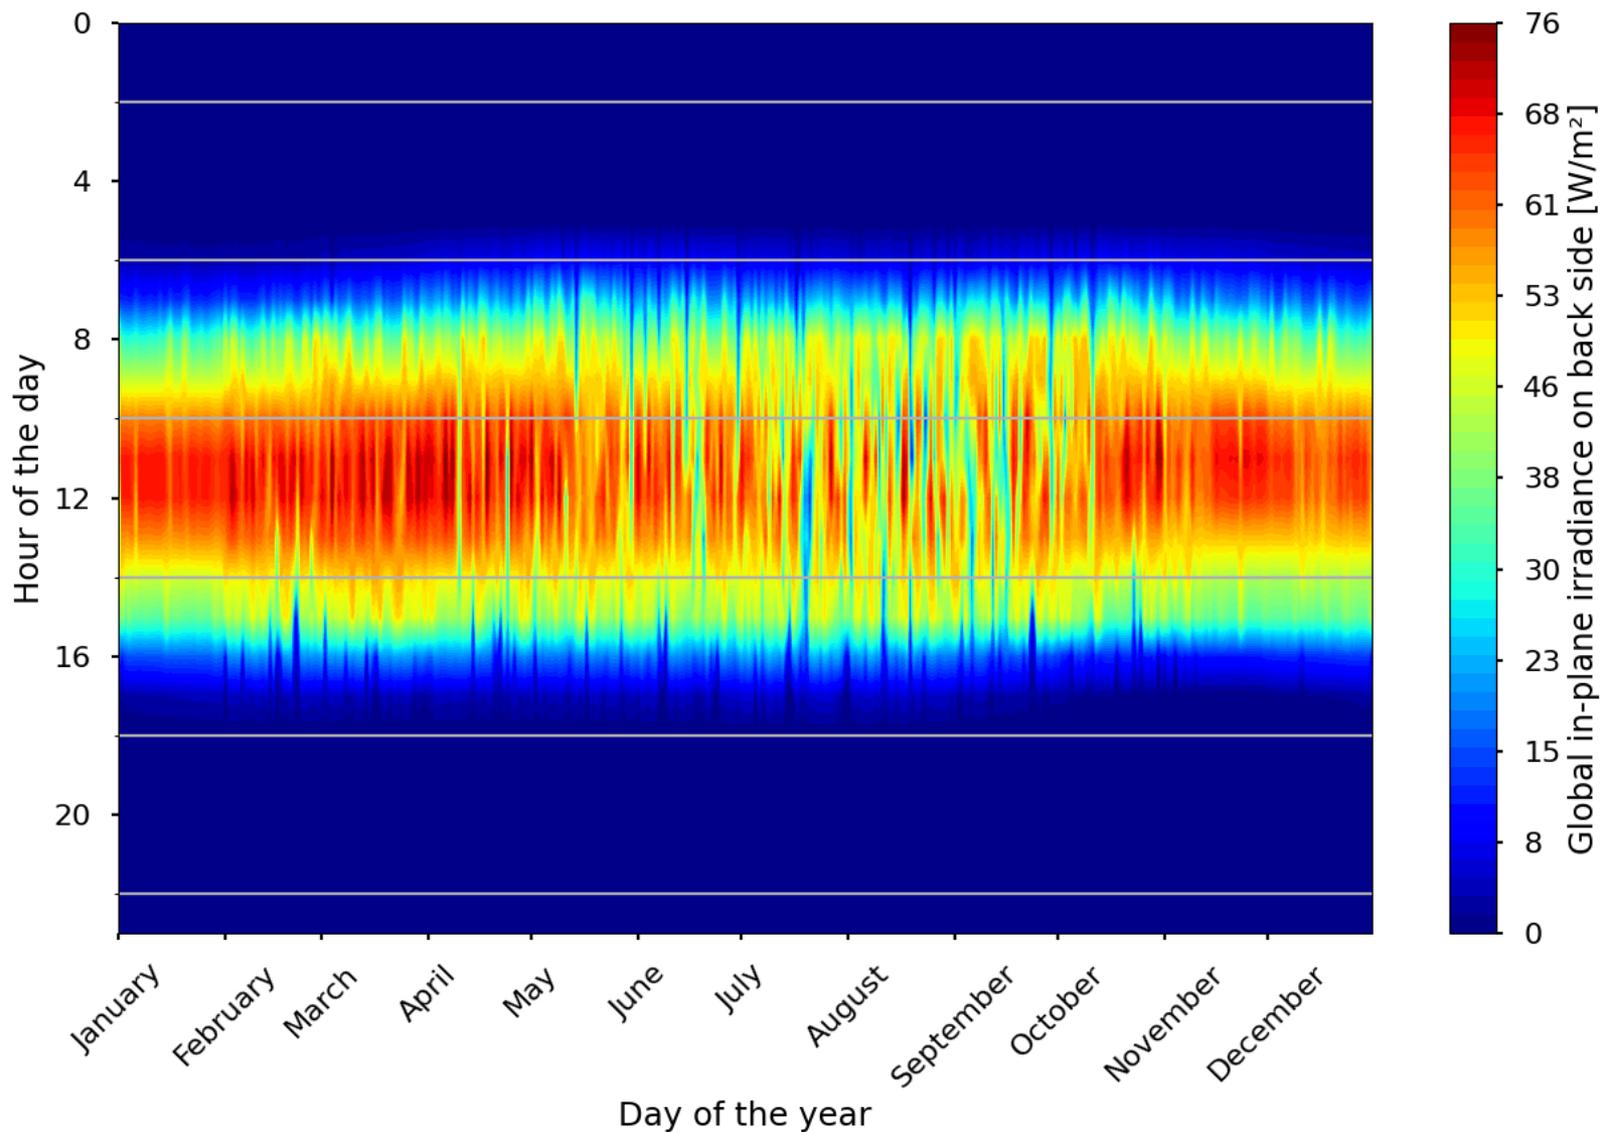

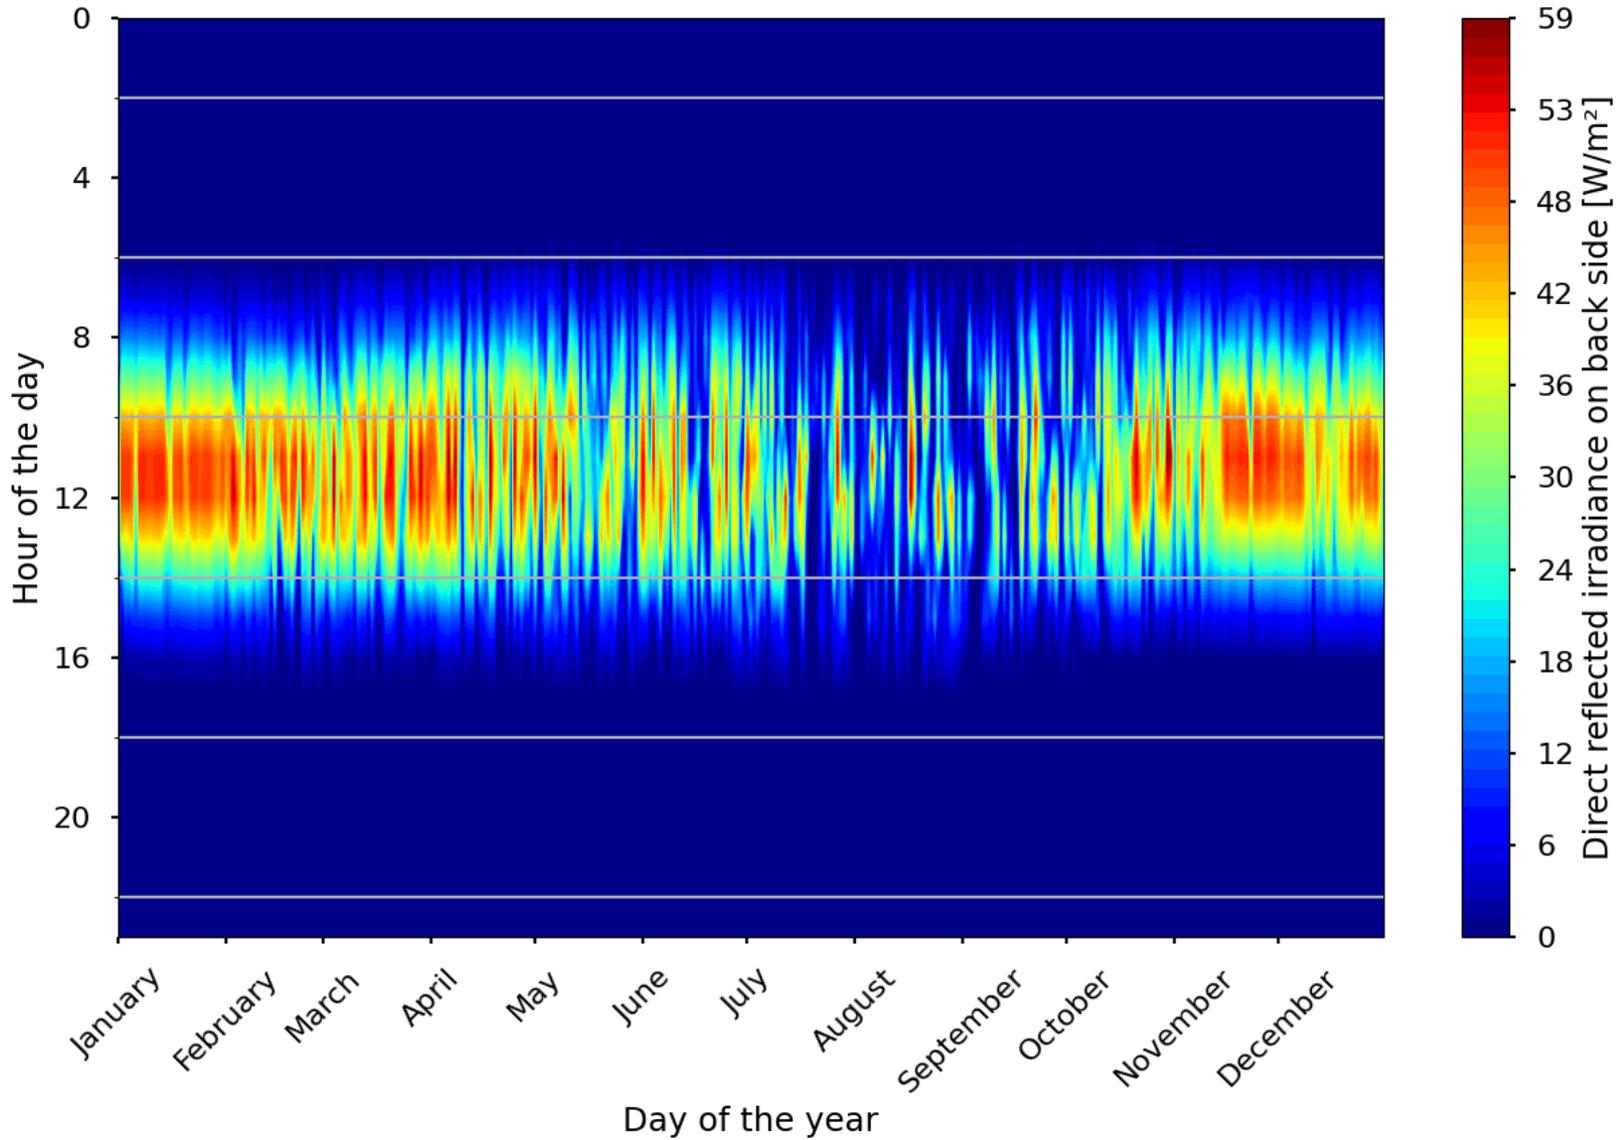

Day with highest Kt: 01 May

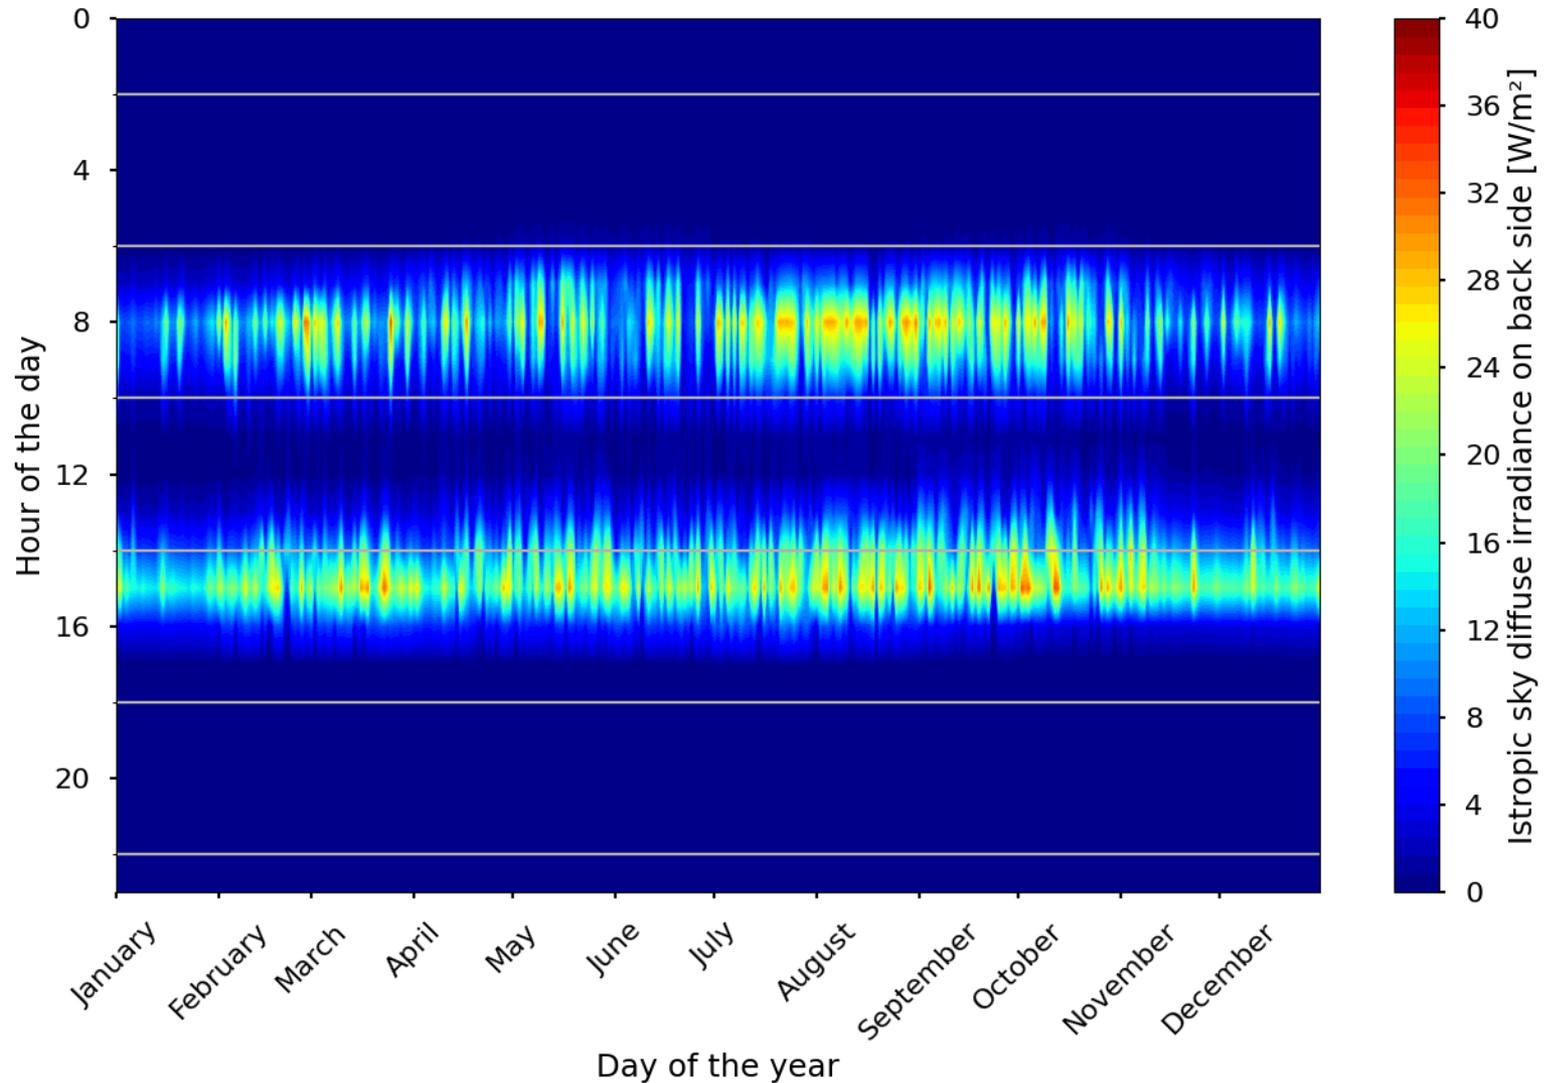

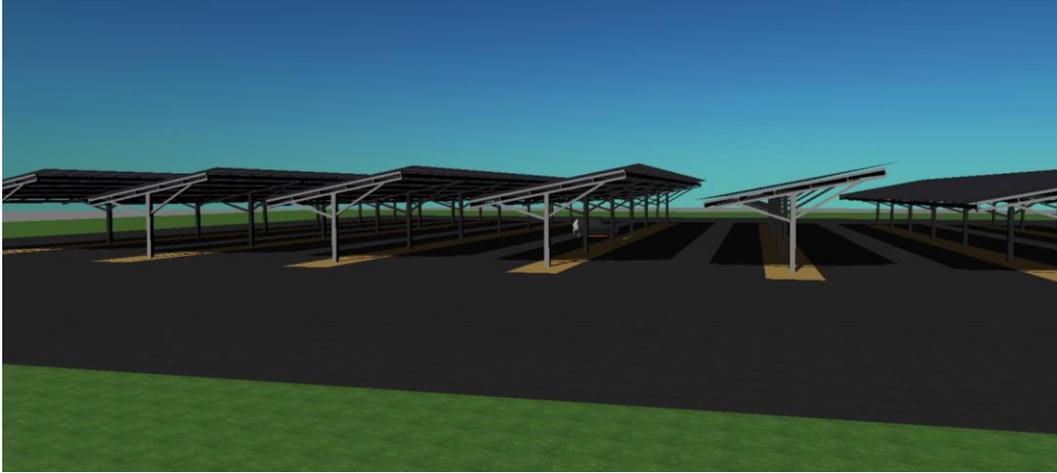

Day with highest Kt: 01 May

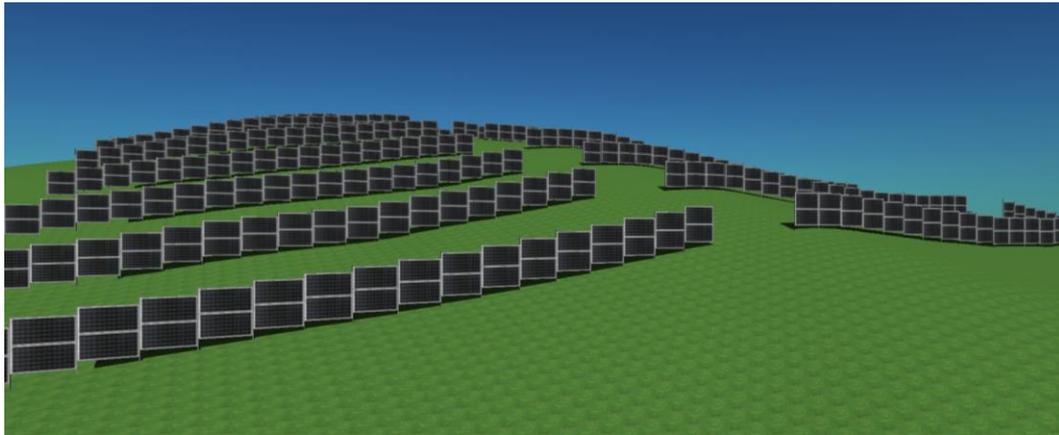

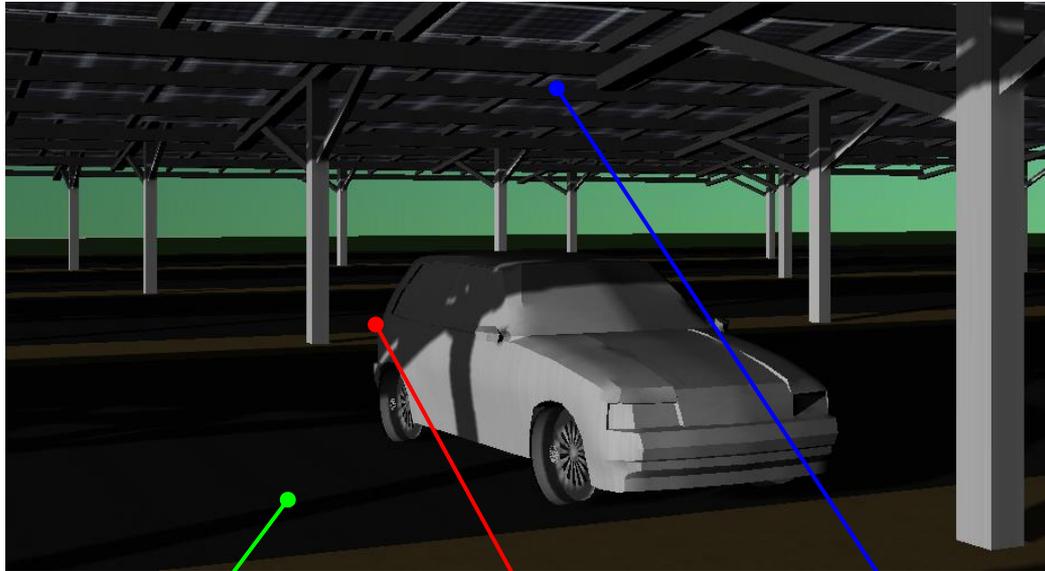

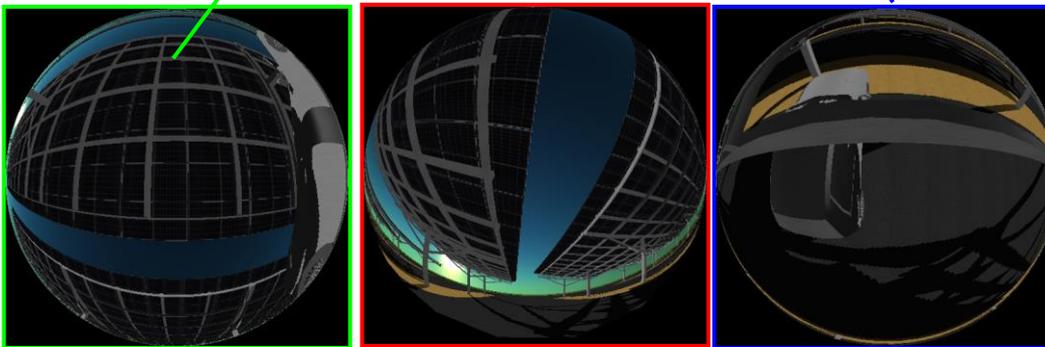

- Different materials and albedos
- Complex structures on the back side
- Impact of other elements than ground
- Reuse of evaluation meshes

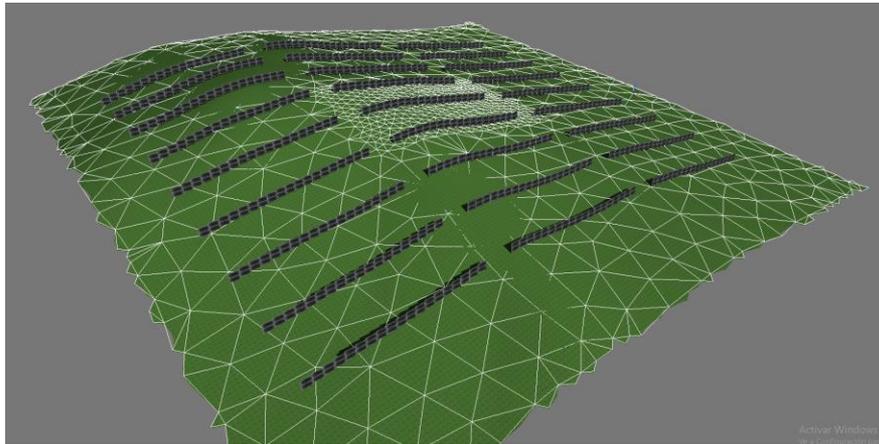

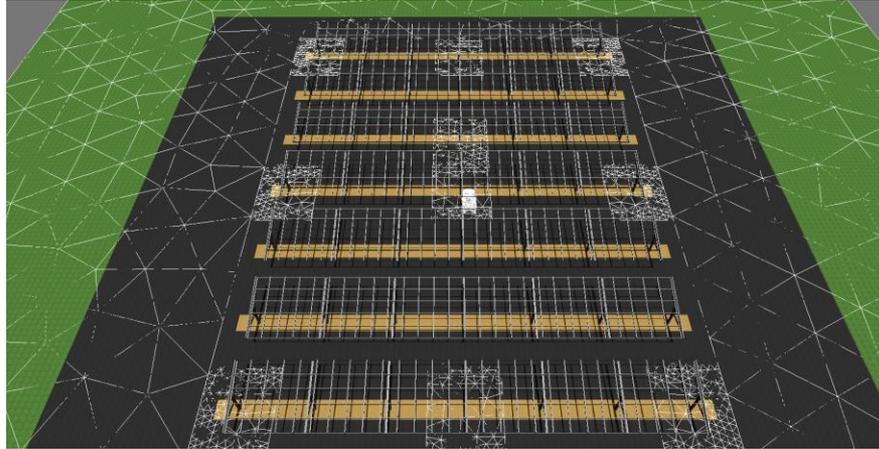

- Installation over irregular terrains
- Undefined “front/back” sides

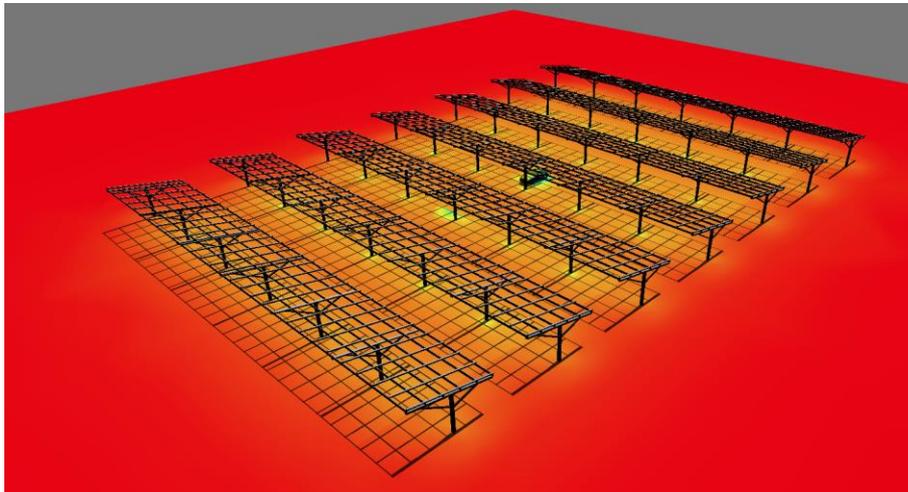

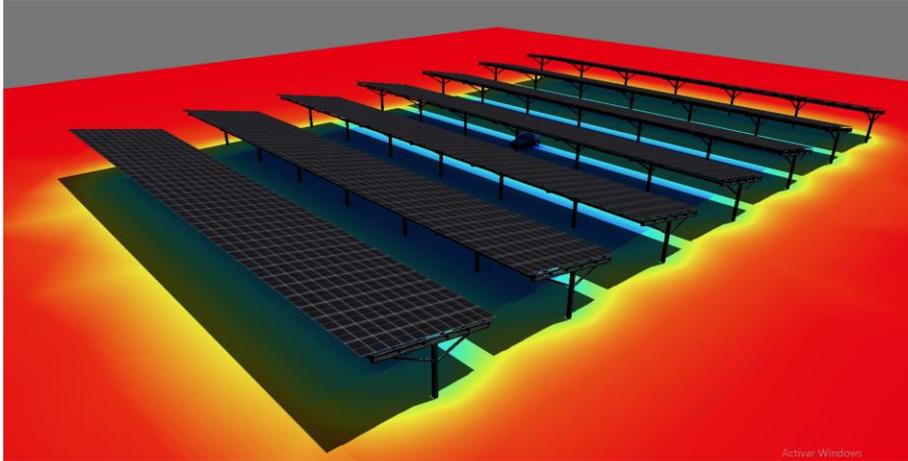

- Current resolution 512x512 pixels
- Pictures generated at different places for different purposes
- Support for debugging analysis
- Scenario evolution capture (sky conditions, sun position, trackers, etc.)
- Evaluation points linked with auxiliary meshes

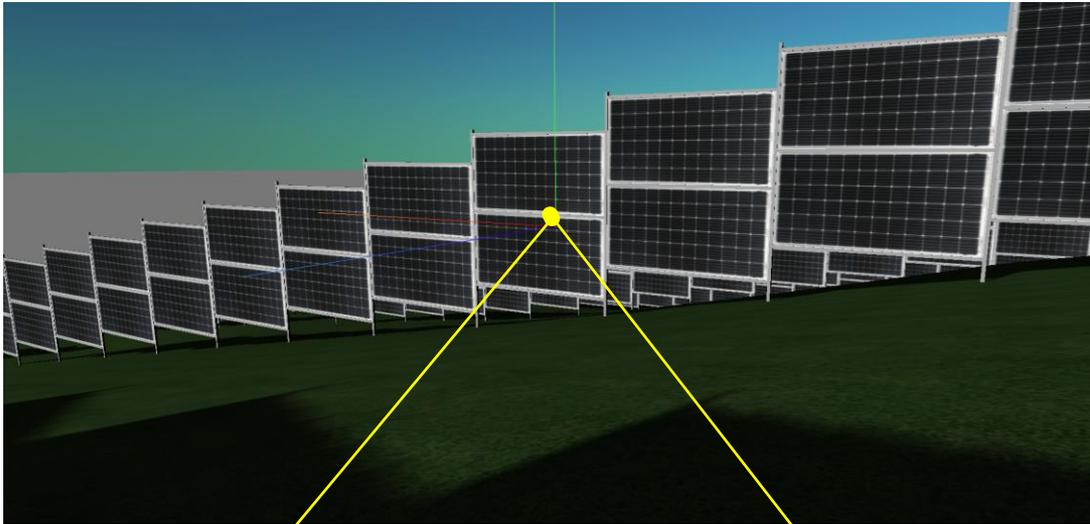

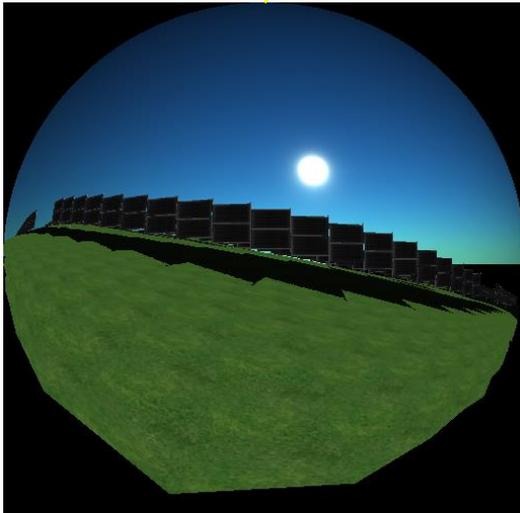

- Support definition for spherical view generation
- Generation through customized software, but standard format
- Adaptable to real surfaces
- Resolution vs computation time control
- Possibility for reuse of areas under a specific pattern (scalability)
- Easy identification of the sources of errors for debugging

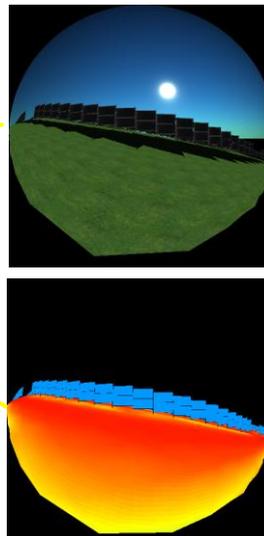

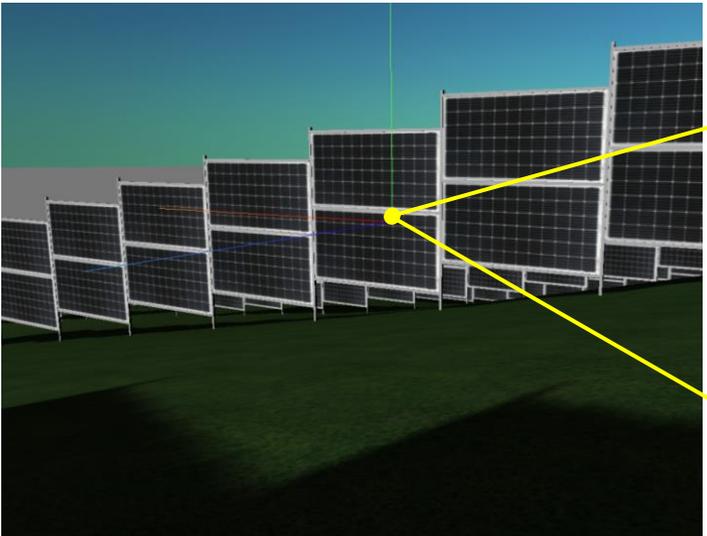

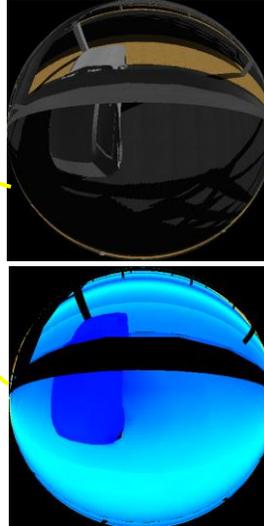

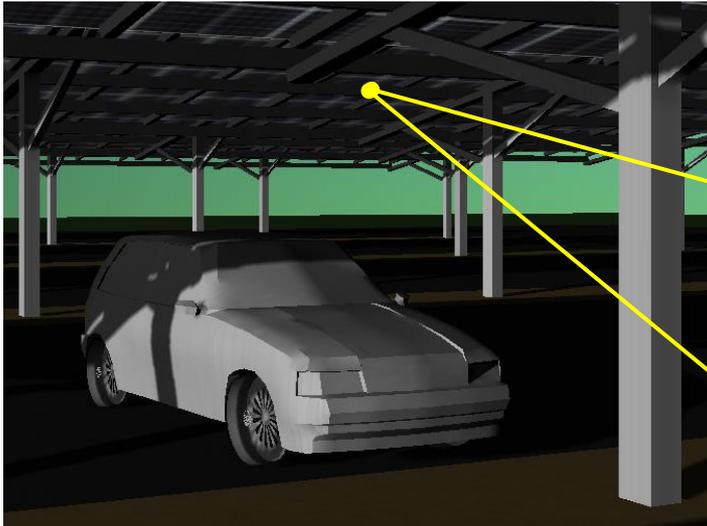

- Objects in the scenario partially block sky visibility (diffuse shading), reducing diffuse irradiance contribution
- Preliminary step to evaluate sky diffuse reflectance potential
- Needs to be adapted to the shape of the objects
- One step calculation for fixed structures, but module rotation dependent for trackers

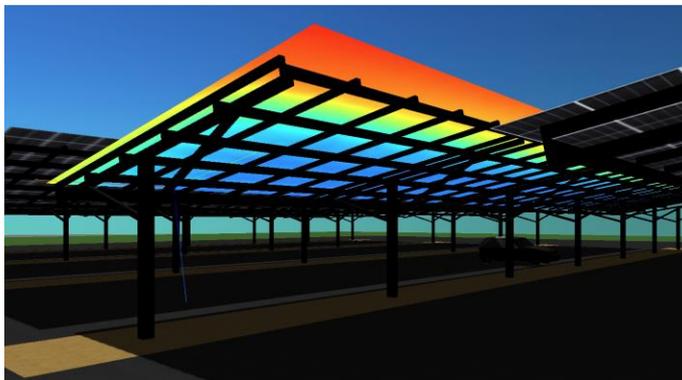

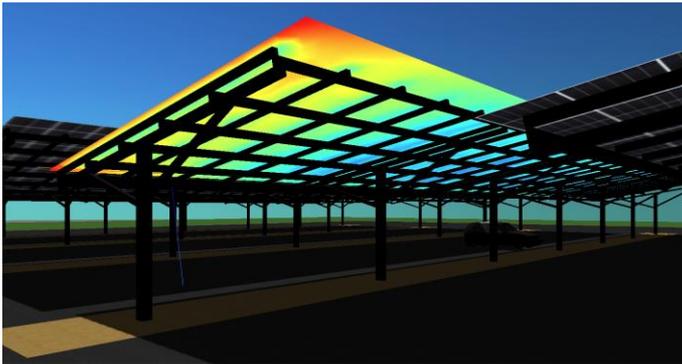

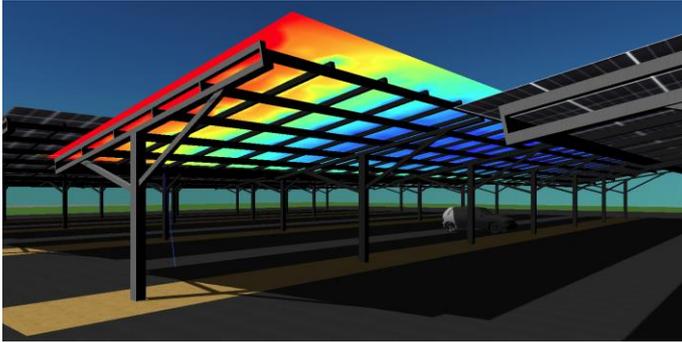

- Identification of the contribution of the pixels in the picture with direct sight of the sky
- Non-uniform irradiance scenarios from sky possible (at pixel level)
- Easy identification of other elements blockage (diffuse shading)
- Larger effect with high tilt angles (maximum for agrivoltaics, marginal for carports)

- Identifies the contribution of the pixels in the picture with reflection of the irradiance from sky
- Includes stationary albedo effects
- Takes into account objects orientation (previous step needed)
- Takes into account possible structure obstructions
- Not dependent on Sun position (computation acceleration; one-step computation for fixed structures)

- Set of spherical view contribution pictures computed per vertex of auxiliary mesh to obtain the local view factor
- After multiplication by different irradiance contributors, we obtain the detailed irradiance breakdown on one side of the PV module
- Information transferred at PV cell level to compute non-homogeneities (mismatch)
- Detailed of structure blockage captured depending on mesh resolution (versus computational time)
